

GoCo: biological relation is used twice — to score functions, and to decide where a calibrated annotation budget is spent

1 Predict (frozen)

gene-GO scores from a
co-essentiality / co-regulation
predictor, plus the sources
that produced each call

2 Calibrate with GoCo

same global grid as GoDag
+ partial admission inside each step,
ordered by predicted loss per
supported term (sources, ranking fold)
certified by fixed-sequence LTT

3 Release more at equal risk

gene-level FDP ≤ 0.10 w.p. $\geq 1-\delta$ (Prop. 1)
supported GO-term yield vs GoDag:
Wainberg: +8.7%
Sanger: +7.6%
DRIVE: +12.8%
HAP1: +6.3%
